

HTTP Client Performance

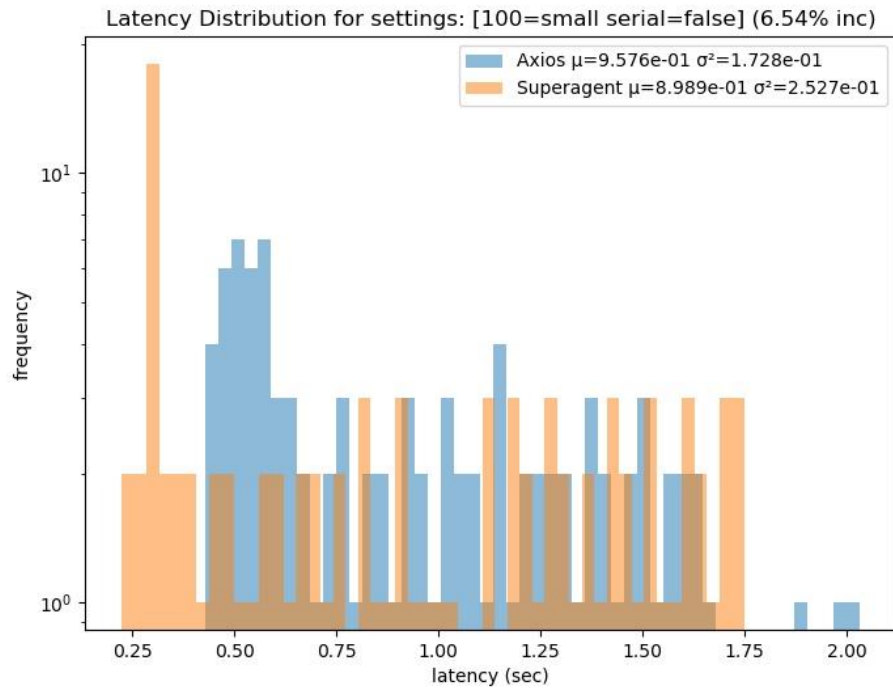

We experimented on Axios's and Superagent's GET functionality and measuring their latency. The parameters of our experiments are the total number of requests and whether or not we're executing them sequentially or concurrently. The title indicates the configuration in the following way: [<# of requests>=<size> serial=<true if sequential>]. The file sizes for small, medium, large are 200kb, 5mb and 200mb.

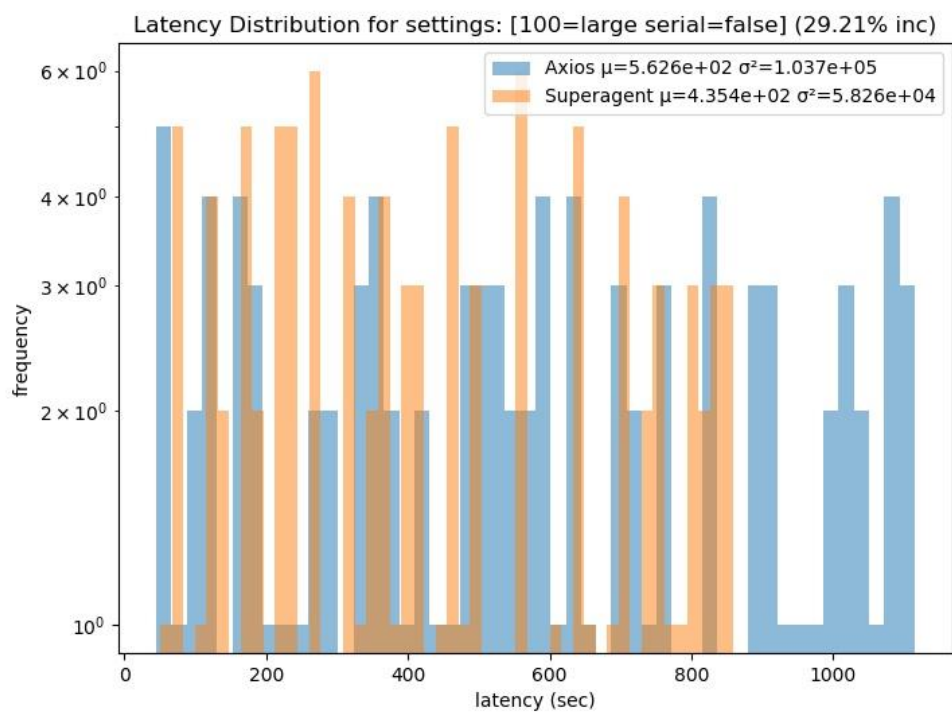

Part 1 – Requests for each experiment are run sequentially.

Part 2 – Requests for each experiment are executed concurrently.

Part 3 – Response time for once all concurrent requests are completed (proportional to throughput). All experiments made 100 requests.
